          Analyzing Operation GhostSecret: Attack Seeks to Steal Data Worldwide
          By Ryan Sherstobitoff and Asheer Malhotra on Apr 24, 2018
      McAfee Advanced Threat Research analysts have uncovered a global data reconnaissance campaign assaulting a wide number of
      industries\ including\ critical\ infrastructure,\ entertainment,\ finance,\ health\ care,\ and\ telecommunications.\ This\ campaign,\ dubbed
      Operation GhostSecret, leverages multiple implants, tools, and malware variants associated with the state-sponsored cyber group
      Hidden Cobra. The infrastructure currently remains active. In this post, we dive deeply into this campaign. For a brief overview of this
      threat, see "Global Malware Campaign Pilfers Data from Critical Infrastructure, Entertainment, Finance, Health Care, and Other
     Our investigation into this campaign reveals that the actor used multiple malware implants, including an unknown implant with
      capabilities similar to Bankshot. From March 18 to 26 we observed the malware operating in multiple areas of the world. This new
      variant resembles parts of the Destover malware, which was used in the 2014 Sony Pictures attack.
      Furthermore, the Advanced Threat Research team has discovered Proxysvc, which appears to be an undocumented implant. We have
      also uncovered additional control servers that are still active and associated with these new implants. Based on our analysis of public
      and private information from submissions, along with product telemetry, it appears Proxysvc was used alongside the 2017 Destover
      The attackers behind Operation GhostSecret used a similar infrastructure to earlier threats, including SSL certificates used by FakeTLS
      in implants found in the Destover backdoor variant known as Escad, which was used in the Sony Pictures attack. Based on our technical properties of the Sony Picture attack. Based on our technical properties of the Sony Picture attack. Based on our technical properties of the Sony Picture attack. Based on our technical properties of the Sony Picture attack.       analysis, telemetry, and data from submissions, we can assert with high confidence that this is the work of the Hidden Cobra group. The analysis is the work of the Hidden Cobra group. The analysis is the work of the Hidden Cobra group and the Hidden Cobra group and the Hidden Cobra group. The third is the work of the Hidden Cobra group and t
      Advanced Threat Research team uncovered activity related to this campaign in March 2018, when the actors targeted Turkish banks.
      These initial findings appear to be the first stage of Operation GhostSecret. For more on the global aspect of this threat, see "Global
      Malware Campaign Pilfers Data from Critical Infrastructure of Entertainment, Finance, Health Care, and Other Industries.
      Analysis
      The McAfee Advanced Threat Research team discovered a previously unknown data-gathering implant that surfaced in mid-February
      2018. This implant appears to be a derivative of implants authored before by Hidden Cobra and contains functionality similar to that of
      Bankshot, with \ code \ overlaps \ from \ other \ Hidden \ Cobra \ implants. \ However, the \ variant \ is \ not \ based \ on \ Bankshot. \ Our \ analysis \ of \ the
      portable executable's rich-header data reveals that the two implants were compiled in different development environments. (The PE
      rich header is an undocumented part of a Windows executable that reveals unique information to identify the Microsoft compiler and
      linker used to create the program. It is helpful for identifying similarities between malware variants to establish common development
      environments.) Our analysis of the code and PE rich header indicates that Bankshot, Proxysvc, and the Destover-like implant are
      distinct families, but also contain overlapping code and functionality with current tools of Hidden Cobra.
      PE rich header data from the 2018 Bankshot implant
      PE rich header data from the new February 2018 implant.
      When we compared the PE rich header data of the new February 2018 implant with a variant of Backdoor. Escad (Destover) from 2014
      shortly before the Sony Pictures attack, we found the signatures to be identical. The Destover-like variant is 83% similar in code to a
      2015 variant and contains the same rich PE header signature as the Backdoor. Escad variant we analyzed. Thus the new implant is likely
      a derivative of components of Destover. We determined that the implant is not a direct copy of well-known previous samples of
      Destover; rather, Hidden Cobra created a new hybrid variant using functionality present in earlier versions.
      2014 Backdoor.Escad (hash: 8a7621dba2e88e32c02fe0889d2796a0c7cb5144).
                                                                                                                                                          prodidMasm613
prodidUtc12_C
prodidLinker600
prodidUtc12_C
      2015 Destover variant (7fe373376e0357624a1d21cd803ce62aa86738b6).
      The \ February \ implant fe 887 fc ab 66 d7 d7 f79 f05 e0 266 c0649 f0114 ba7c \ was obtained \ from \ an \ unknown \ submitter \ in \ the \ United \ States \ on \ an \ for \ for
      February 14, two days after it was compiled. This Korean-language file used the control server IP address 203.131.222.83. The implant is
      nearly identical to an unknown 2017 sample (8f2918c721511536d8c72144eabaf685ddc21a35) except that the control server addresses
      are different. The 2017 sample used address 14.140.116.172. Both implants specifically use FakeTLS with PolarSSL, which we saw in
      previous Hidden Cobra implants, PolarSSL libraries have appeared in implants since the Sony Pictures incident and were used
      exclusively in the implant Backdoor. Destover. This implant incorporated a custom control server protocol that sends traffic over port
      443. The implementation does not format the packets in standard SSL, but rather in a custom format and transmitted over SSL—hence,
      \begin{tabular}{ll} \hline Fake TLS. The control server traffic when compared to Backdoor. Escad is nearly identical. \\ \hline \hline \end{tabular}
      ...L...H. Z.HG. 1...|.F.q.R.C....6.NcH...3.9.5./......????????????...M...I..F..C0..?0..'.....0
      TLS traffic in Backdoor. Destover, the 2018 Destover-like variant.
       .I..E.S.Kh...h.s..w...3.q...pzAc...3.9.5./......-l@#$%^&*()...M..I.F.C0.70..'....0
      TLS traffic in Backdoor.Escad.
      Further research into IP address 14.140.116.172 leads us to additional hidden components involved in the overall infrastructure.
      Proxysvc.dll contains a list of hardcoded IP addresses, including the preceding address, all located in India. Despite the name, this
      component is not an SSL proxy, but rather a unique data-gathering and implant-installation component that listens on port 443 for
      Proxysvc was first collected by public and private sources on March 22 from an unknown entity in the United States. The executable
      dropper for the component was submitted from South Korea on March 19. McAfee telemetry analysis from March 16 to 21 reveals that
      Proxysvc components were active in the wild. Our research shows this listener component appeared mostly in higher education
      organizations. We suspect this component is involved in core control server infrastructure. These targets were chosen intentionally to
      run Proxysyc because the attacker would have needed to know which systems were infected to connect to them. This data also
      indicates this infrastructure had been operating for more than a year before its discovery. The Advanced Threat Research team found
      this component running on systems in 11 countries. Given the limited capabilities of Proxysvc, it appears to be part of a covert network
      of SSL listeners that allow the attackers to gather data and install more complex implants or additional infrastructure. The SSL listener
      supports multiple control server connections, rather than a list of hardcoded addresses. By removing the dependency on hardcoded IP
      addresses and accepting only inbound connections, the control service can remain unknown
                                 GLOBAL INFECTIONS OF PROXYSVC.DLL
      The number of infected systems by country in which Proxysvc.dll was operating in March. Source: McAfee Advanced Threat Research.
      The 2018 Destover-like implant appeared in organizations in 17 countries between March 14 and March 18. The impacted organizations
      are in industries such as telecommunications, health, finance, critical infrastructure, and entertainment.
                                                  Global Infections of Destover Variant

      Research.
      Control Servers
      Further investigation into the control server infrastructure reveals the SSL certificate d0cb9b2d4809575e1bc1f4657e0eb56f307c7a76,
      which is tied to the control server 203.131.222.83, used by the February 2018 implant. This server resides at Thammasat University in
      Bangkok, Thailand. The same entity hosted the control server for the Sony Pictures implants. This SSL certificate has been used in
      Hidden Cobra operations since the Sony Pictures attack. Analyzing this certificate reveals additional control servers using the same
      Polar SSL\ certificate.\ Further\ analysis\ of\ McAfee\ telemetry\ data\ reveals\ several\ IP\ addresses\ that\ are\ active,\ two\ within\ the\ same\ network\ analysis\ of\ McAfee\ telemetry\ data\ reveals\ several\ IP\ addresses\ that\ are\ active,\ two\ within\ the\ same\ network\ analysis\ of\ McAfee\ telemetry\ data\ reveals\ several\ IP\ addresses\ that\ are\ active,\ two\ within\ the\ same\ network\ analysis\ of\ McAfee\ telemetry\ data\ reveals\ several\ IP\ addresses\ that\ are\ active,\ two\ within\ the\ same\ network\ analysis\ of\ McAfee\ telemetry\ data\ reveals\ several\ IP\ addresses\ that\ are\ active,\ two\ within\ the\ same\ network\ analysis\ of\ McAfee\ telemetry\ data\ reveals\ several\ IP\ addresses\ that\ are\ active\ two\ within\ the\ same\ network\ analysis\ a

      Implant Origins
      McAfee Advanced Threat Research determined that the Destover-like variant originated from code developed in 2015. The code
     reappeared in variants surfacing in 2017 and 2018 using nearly the same functionality and with some modifications to commands,
      along with an identical development environment based on the rich PE header information.
      Both implants (fe887 fcab 66 d7 d7 f79 f05 e026 6c0649 f0114 ba7c \ and \ 8 f2918 c721511536 d8 c72144 eabaf685 ddc21a35) \ are \ based \ on \ the \ 2015 and \ 4 f2918 c721511536 d8 c7214 abaf685 ddc21a35) \ are \ based \ on \ the \ 2015 and \ 2015 an
      code. When comparing the implant 7fe373376e0357624a1d21cd803ce62aa86738b6, compiled on August 8, 2015, we found it 83%
      similar to the implant from 2018. The key similarities and differences follow.
      Similarities

    Both variants build their API imports dynamically using GetProcAddress, including wtsapi32.dll for gathering user and domain names

          for any active remote sessions

    Both variants contain a variety of functionalities based on command IDs issued by the control servers

      · Common capabilities of both malware:

    Listing files in directory

    Creating arbitrary processes

    Writing data received from control servers to files on disk

            • Gathering information for all drives
           • Gathering process times for all processes
           • Sending the contents of a specific file to the control server
           · Wiping and deleting files on disk
           · Setting the current working directory for the implant
           • Sending disk space information to the control server

    Both variants use a batch file mechanism to delete their binaries from the system

    Both variants run commands on the system, log output to a temporary file, and send the contents of the file to their control servers

      The following capabilities in the 2015 implant are missing from the 2018 variant:
      • Creating a process as a specific user
      • Terminating a specific process

    Getting current system time and sending it to the control server

      • Reading the contents of a file on disk. If the filepath specified is a directory, then listing the directory's contents.
      · Setting attributes on files
      The 2015 implant does not contain a hardcoded value of the IP address it must connect to. Instead it contains a hardcoded sockaddr_in
      data structure (positioned at 0x270 bytes before the end of the binary) used by the connect() API to specify port 443 and control server
      • 193.248.247.59
      Both of these control servers used the PolarSSL certificate d0cb9b2d4809575e1bc1f4657e0eb56f307c7a76.
      Proxysvc
      At first glance Proxysvc, the SSL listener, looks like a proxy setup tool (to carry out man-in-the-middle traffic interception). However, a
      closer\ analysis\ of\ the\ sample\ reveals\ it\ is\ yet\ another\ implant\ using\ HTTP\ over\ SSL\ to\ receive\ commands\ from\ the\ control\ server.
      Proxysvc appears to be a downloader whose primary capability is to deliver additional payloads to the endpoint without divulging the
      control address of the attackers. This implant contains a limited set of capabilities for reconnaissance and subsequent payload
      installations. This implant is a service DLL that can also run as a standalone process.

                                                  call.
      Proxysvc begins accepting incoming requests to process.
      Proxysvc makes an interesting check while accepting connections from a potential control server. It checks against a list of IP addresses
      to make sure the incoming connection is not from any of the following addresses. If the incoming request does come from one of these,
     the implant offers a zero response (ASCII "0") and shuts down the connection.

    Product name from HKLM\Software\Microsoft\Windows NT\CurrentVersion ProductName

                                                                                                                                                                                                          Name | ProductName" and is sent to
       • Recording HTTP requests from the control server to the temporary file prx in the implant's install directory with the current system
      Analyzing the Main Implant
      The February 2018 implant contains a wide variety of capabilities including data exfiltration and arbitrary command execution on the
      victim's system. Given the extensive command structure that the implant can receive from the control server, this is an extensive
      framework for data reconnaissance and exfiltration, and indicates advanced use. For example, the implant can wipe and delete files
      execute additional implants, read data out of files, etc.
      The implant begins execution by dynamically loading APIs to perform malicious activities. Libraries used to load the APIs include:

    Apvapi32.dll

    Oleaut32.dll

    Iphlpapi.dll

    Ws2_32.dll

      • Wtsapi32.dll

    Ntdll.dll

                                               The main implant dynamically loading APIs.
      As part of its initialization, the implant gathers basic system information and sends it to its hardcoded control server 203.131.222.83
      • Country name from system's locale
      • Operating system version

      Conclusion
      This analysis by the McAfee Advanced Threat Research team has found previously undiscovered components that we attribute to
      Hidden Cobra, which continues to target organizations around the world. The evolution in complexity of these data-gathering implants
      reveals an advanced capability by an attacker that continues its development of tools. Our investigation uncovered an unknown
      infrastructure\ connected\ to\ recent\ operations\ with\ servers\ in\ India\ using\ an\ advanced\ implant\ to\ establish\ a\ covert\ network\ to\ gather
      The McAfee Advanced Threat Research team will provide further updates as our investigation develops.
      Fighting cybercrime is a global effort best undertaken through effective partnerships between the public and private sectors. McAfee is
       working with Thai government authorities to take down the control server infrastructure of Operation GhostSecret, while preserving
      the systems involved for further analysis by law enforcement authorities. By creating and maintaining partnerships with worldwide law
      enforcement, McAfee demonstrates that we are stronger together.
      Indicators of Compromise
      MITRE ATT&CK techniques
      • Exfiltration over control server channel: data is exfiltrated over the control server channel using a custom protocol
      • Commonly used port: the attackers used common ports such as port 443 for control server communications
      • Service execution: registers the implant as a service on the victim's machine
      · Automated collection: the implant automatically collects data about the victim and sends it to the control server
      • Data from local system: local system is discovered and data is gathered
      • Process discovery: implants can list processes running on the system
       • System time discovery: part of the data reconnaissance method, the system time is also sent to the control server
      • File deletion: malware can wipe files indicated by the attacker
